## PARENTHETIC REMARKS

## Ross Street

Macquarie University, N S W<br>2109<br>AUSTRALIA<br>Email [street@math.mq.edu.au](mailto:street@math.mq.edu.au)

The purpose of this note is to provide a gentle ${ }^{1}$ introduction to operads and other related areas of contemporary mathematics by concentrating on an important example: the process of parenthesising.

The bracketing ${ }^{2}$ of a string abcde of entities $a, b, c, d, e$ should produce a new entity (abcde). This example shows bracketing as an operation of arity 5 . We do not allow () or (a). This leads us to the following notion of universal algebra. A parengebra is a set A together with, for all $n \geq 2$, exactly one $n$-ary operation

$$
\beta_{\mathrm{n}}: \mathrm{A}^{\mathrm{n}} \longrightarrow \mathrm{~A}
$$

subject to no axioms. Let $\mathcal{K}$ denote the category of parengebras and their homomorphisms. The general associativity law implies that every semigroup is canonically a parengebra. In particular, we have the parengebra $\mathbb{N}$ of natural numbers under addition

$$
\beta_{\mathrm{n}}\left(\mathrm{~m}_{1}, \ldots, \mathrm{~m}_{\mathrm{n}}\right)=\mathrm{m}_{1}+\ldots+\mathrm{m}_{\mathrm{n}} .
$$

Write $F(X)$ for the free parengebra on the set $X$. The elements of $F(X)$ are built up iteratively as follows:
(i) each $x \in X$ is in $F(X)$;
(ii) if $a_{1}, \ldots, a_{n} \in F(X)$ for $n \geq 2$ then $\beta_{n}\left(a_{1}, \ldots, a_{n}\right) \in F(X)$.

Writing $\left(a_{1} \ldots a_{n}\right)$ for $\beta_{n}\left(a_{1}, \ldots, a_{n}\right)$, we can imagine elements of $F(X)$ as words in $X$ (that is, elements of the free monoid $\mathrm{X}^{*}$ on X ) with brackets meaningfully inserted. This provides the left adjoint functor $\mathrm{F}:$ Set $\longrightarrow \mathcal{K}$ to the forgetful functor $\mathrm{U}: \mathcal{K} \longrightarrow$ Set into the category Set of small sets. Let $\mathrm{K}=\mathrm{U} \circ \mathrm{F}:$ Set $\longrightarrow$ Set be the monad on Set generated by the adjunction $\mathrm{F} \dashv \mathrm{U}$. As with any forgetful functor from a category of universal algebras, the functor $\mathrm{U}: \mathcal{K} \longrightarrow$ Set is monadic; we have an isomorphism of categories

$$
\mathcal{K} \cong \operatorname{Set}^{\mathrm{K}},
$$

where Set $^{K}$ is the category of Eilenberg-Moore K-algebras. The concepts needed here can be found in [ML].

Consider the functor $\mathrm{R}:$ Set $\longrightarrow$ Set given by the power series

[^0]$$
R(X)=\sum_{n \geq 2} X^{n}
$$

As with any endofunctor, an R-algebra is an object $A$ of the category (Set in this case) together with an arrow $\beta: R(A) \longrightarrow A$, which in this case is the same as a parengebra. Write $\operatorname{Set}^{\mathrm{R}}$ for the category of R -algebras; we have the trivial identification:

$$
\mathcal{K}=\operatorname{Set}^{\mathrm{R}}
$$

It follows that $K$ is the free (pointwise) monad on the endofunctor $R$. As such, $K$ is expressible as a power series; that is, there is a sequence $k_{0}, k_{1}, k_{2}, \ldots$ of sets and a natural bijection

$$
K(X) \cong \mathrm{k}_{0}+\mathrm{k}_{1} \times \mathrm{X}+\mathrm{k}_{2} \times \mathrm{X}^{2}+\mathrm{k}_{3} \times \mathrm{X}^{3}+\ldots .
$$

We can take the set $k_{n}$ to consist of meaningfully bracketed words of length $n$. More precisely, we can find the sets $\mathrm{k}_{\mathrm{n}}$ using the philosophy of clubs [K1]. This leads to the expectation that the functor $K$ can be recaptured from the free parengebra $k=F(1)$ on the singleton set 1 augmented by some "grounding" homomorphism. Let $\gamma: k \longrightarrow \mathbb{N}$ be the unique parengebra homomorphism taking the element of the generating set 1 to the natural number 1. This gives a grading of $k$ according to the number of occurrences of the generator in the bracketed word; that is,

$$
\mathrm{k}_{\mathrm{n}}=\gamma^{-1}(\mathrm{n}) .
$$

For any set $X$, the iterative construction of $F(X)$ given by (i), (ii) can be interpreted as a bijection

$$
K(X) \cong X+K(X)^{2}+K(X)^{3}+K(X)^{4}+K(X)^{5}+\ldots .
$$

These are the components of a natural isomorphism

$$
K \cong 1_{S e t}+R \circ K
$$

between endofunctors of Set. Moreover, we can apply a virtual sets argument to the bijection of the last paragraph to obtain a "formula" for the $\mathrm{k}_{\mathrm{n}}$ as mere sets. Put $\mathrm{Y}=\mathrm{K}(\mathrm{X})$ so that the bijection becomes:

$$
Y \cong X+Y^{2}+Y^{3}+Y^{4}+Y^{5}+\ldots \cong X+Y^{2} \times(1-Y)^{-1}
$$

Multiplying on the right by $(1-\mathrm{Y})^{-1}$ and rearranging, we obtain the quadratic isomorphism

$$
2 Y^{2}-(1+X) \times Y+X \cong 0
$$

Solving by radicals and choosing the meaningful minus sign, we obtain

$$
Y \cong \frac{1}{4}\left(1+X-\left(1-6 X+X^{2}\right)^{\frac{1}{2}}\right)
$$

Applying the binomial theorem, we deduce a bijection

$$
K(X) \cong X+X^{2}+3 X^{3}+11 X^{4}+45 X^{5}+\ldots
$$

If the reader is suspicious of virtual sets, at least this argument is valid in terms of generating functions and so gives the cardinalities of $\mathrm{k}_{0}, \mathrm{k}_{1}, \mathrm{k}_{2}, \mathrm{k}_{3}, \mathrm{k}_{4}, \mathrm{k}_{5}, \ldots$ as

$$
0,1,1,3,11,45, \ldots
$$

As an example, we see that for $k_{4}$ there are the eleven bracketings occurring as in the Stasheff pentagon $\mathrm{K}_{4}$ :

From this cell complex representation, we see that it is natural to define the dimension of an element $a \in F(X)$ to be $n-2$ where $n$ is the largest natural number for which $\beta_{n}$ occurs in the iterative construction of a from elements of $X$. It is also natural to define the boundary $\partial(a)$ of $a \in F(X)$ to be the subset of $F(X)$ consisting of those elements obtained from a by meaningfully inserting precisely one further pair of brackets. There is a partial order on $F(X)$ generated by $a \leq b$ if $a \in \partial(b)$. The dimension $n$ of $a \in F(X)$ is the length of $a$ maximal descending chain $a>a_{1}>a_{2}>\ldots>a_{n}$.

The Stasheff pentagon arose in homotopy theory, specifically, in studying the structure borne by loop spaces. This study was further advanced by May [M] who introduced the concept of operad. We shall see that our sequence $k=\left(k_{n}\right)$ of sets is indeed a planar (or non-permutative) operad.

Given two sequences $\mathrm{p}, \mathrm{q}$ of sets, we define their substitution product $\mathrm{p} \circ \mathrm{q}$ to be the sequence of sets

$$
(p \circ q)_{n}=\sum_{m_{1}+\ldots+m_{i}=n} p_{i} \times q_{m_{1}} \times \ldots \times q_{m_{i}}
$$

We regard a sequence p of sets as a functor from the discrete category $\mathbb{N}$, whose objects are natural numbers, to the category Set. The substitution product defines a monoidal structure on the category $\operatorname{Set}^{\mathbb{N}}$ of sequences of sets; the unit for substitution is the sequence $u$ with $u_{1}$ a singleton set and $u_{n}=\varnothing$ for $n \neq 1$.

A (planar) operad $t$ is a monoid for the substitution product on $\operatorname{Set}^{\mathbb{N}}$. Notice that the unit for such a monoid is an element $1 \in \mathfrak{t}_{1}$ and the multiplication amounts to a collection of functions

$$
\mathrm{t}_{\mathrm{i}} \times \mathrm{t}_{\mathrm{m}_{1}} \times \mathrm{t}_{\mathrm{m}_{2}} \times \ldots \times \mathrm{t}_{\mathrm{m}_{\mathrm{i}}} \longrightarrow \mathrm{t}_{\mathrm{m}_{1}+\mathrm{m}_{2}+\ldots+\mathrm{m}_{\mathrm{i}}}
$$

whose value at $\left(\tau, \tau_{1}, \ldots, \tau_{\mathrm{i}}\right)$ is denoted by $\tau\left[\tau_{1}, \ldots, \tau_{\mathrm{i}}\right]$, called the result of substituting $\tau_{1}, \ldots, \tau_{\mathrm{i}}$ in $\tau$, such that

$$
\left.\begin{array}{c}
1\left[\tau_{1}\right]=\tau_{1}, \quad \tau[1, \ldots, 1]=\tau \\
\tau\left[\tau_{1}\left[\tau_{11}, \ldots, \tau_{1 \mathrm{j}_{1}}\right], \ldots, \tau_{\mathrm{i}}\left[\tau_{\mathrm{i} 1}, \ldots, \tau_{\mathrm{i} \mathrm{j}_{1}}\right]\right]=\tau\left[\tau_{1}, \ldots, \tau_{\mathrm{i}}\right]\left[\tau_{11}, \ldots, \tau_{1 \mathrm{j}_{1}}, \ldots, \tau_{\mathrm{i} 1}, \ldots, \tau_{\mathrm{ij}} \mathrm{i}\right.
\end{array}\right] .
$$

An operad morphism is just a monoid morphism in $\operatorname{Set}^{\mathbb{N}}$ with substitution tensor product.

Example 1 Let $\mathcal{A}$ be a monoidal category. Each object A of $\mathcal{A}$ gives rise to an operad t $=\mathcal{A}(\mathrm{A})$, where $\mathrm{t}_{\mathrm{n}}=\mathcal{A}\left(\mathrm{A}^{\otimes \mathrm{n}}, \mathrm{A}\right)$, and substitution

$$
\mathcal{A}\left(\mathrm{A}^{\otimes \mathrm{i}}, \mathrm{~A}\right) \times \mathcal{A}\left(\mathrm{A}^{\otimes \mathrm{m}_{1}}, \mathrm{~A}\right) \times \ldots \times \mathcal{A}\left(\mathrm{A}^{\otimes \mathrm{m}_{\mathrm{i}}}, \mathrm{~A}\right) \longrightarrow \mathcal{A}\left(\mathrm{A}^{\otimes \mathrm{n}}, \mathrm{~A}\right)
$$

is given by $\left(f, g_{1}, \ldots, g_{i}\right) \longmapsto \mathrm{f} \circ\left(\mathrm{g}_{1} \otimes \ldots \otimes \mathrm{~g}_{\mathrm{i}}\right)$. The distinguished element of $\mathrm{t}_{1}$ is of course the identity arrow of $A$.

Example 2 Every operad t determines a strict monoidal category $\mathcal{V}_{\mathrm{t}}$ as follows. The objects are the natural numbers and the homsets are given by

$$
\mathcal{V}_{\mathrm{t}}(\mathrm{~m}, \mathrm{n})=\sum_{\mathrm{m}_{1}+\ldots+\mathrm{m}_{\mathrm{n}}=\mathrm{m}}^{\mathrm{t}_{\mathrm{m}_{1}} \times \ldots \times \mathrm{t}_{\mathrm{m}_{\mathrm{n}}} .}
$$

Composition

$$
\mathcal{V}_{\mathrm{t}}(\mathrm{n}, \mathrm{j}) \times \mathcal{V}_{\mathrm{t}}(\mathrm{~m}, \mathrm{n}) \longrightarrow \mathcal{V}_{\mathrm{t}}(\mathrm{~m}, \mathrm{j})
$$

takes $\left(\tau_{\mathrm{n}_{1}}, \ldots, \tau_{\mathrm{n}_{j}}, \tau_{\mathrm{m}_{1}}, \ldots, \tau_{\mathrm{m}_{\mathrm{n}}}\right) \in \mathrm{t}_{\mathrm{n}_{1}} \times \ldots \times \mathrm{t}_{\mathrm{n}_{\mathrm{j}}} \times \mathrm{t}_{\mathrm{m}_{1}} \times \ldots \times \mathrm{t}_{\mathrm{m}_{\mathrm{n}}}$ to

$$
\left(\tau_{\mathrm{n}_{1}}\left[\tau_{\mathrm{m}_{1}}, \ldots, \tau_{\mathrm{m}_{\mathrm{n}_{1}}}\right], \tau_{\mathrm{n}_{2}}\left[\tau_{\mathrm{m}_{\mathrm{n}_{1}+1}}, \ldots, \tau_{\mathrm{m}_{\mathrm{n}_{1}+\mathrm{n}_{2}}}\right], \ldots, \tau_{\mathrm{n}_{\mathrm{j}}}\left[\tau_{\mathrm{m}_{\mathrm{n}-\mathrm{n}_{\mathrm{j}}+1}}, \ldots, \tau_{\mathrm{m}_{\mathrm{n}}}\right]\right)
$$

where $\mathrm{m}_{1}+\ldots+\mathrm{m}_{\mathrm{n}}=\mathrm{m}$ and $\mathrm{n}_{1}+\ldots+\mathrm{n}_{\mathrm{j}}=\mathrm{n}$. The tensor product of $\mathcal{V}_{\mathrm{t}}$ is given on objects by addition and on homsets

$$
\mathcal{V}_{\mathrm{t}}(\mathrm{~m}, \mathrm{n}) \times \mathcal{V}_{\mathrm{t}}(\mathrm{i}, \mathrm{j}) \longrightarrow \mathcal{V}_{\mathrm{t}}(\mathrm{~m}+\mathrm{i}, \mathrm{n}+\mathrm{j})
$$

by $\quad\left(\left(\tau_{\mathrm{m}_{1}}, \ldots, \tau_{\mathrm{m}_{\mathrm{n}}}\right),\left(\tau_{\mathrm{i}_{1}}, \ldots, \tau_{\mathrm{i}_{\mathrm{j}}}\right)\right) \longmapsto\left(\tau_{\mathrm{m}_{1}}, \ldots, \tau_{\mathrm{m}_{\mathrm{n}}}, \tau_{\mathrm{i}_{1}}, \ldots, \tau_{\mathrm{i}_{\mathrm{j}}}\right)$. Clearly we recapture the original operad $t$ from the object $1 \in \mathcal{V}_{t}$ by the construction of Example 1. Furthermore, for any strict monoidal category $\mathcal{A}$ and $\mathrm{A} \in \mathcal{A}$, the operad morphisms $\phi: \mathrm{t} \longrightarrow \mathcal{A}(\mathrm{A})$ are in bijection with the strict monoidal functors $\mathrm{M}: \mathcal{V}_{\mathrm{t}} \longrightarrow \mathcal{A}$ with $\mathrm{M}(1)=\mathrm{A}$; the bijection is determined by putting $\mathrm{M}(\mathrm{n})=\mathrm{A}^{\otimes \mathrm{n}}$ and taking the effect of M on the homsets $\mathcal{V}_{\mathrm{t}}(\mathrm{n}, 1)$ $\longrightarrow \mathcal{A}(\mathrm{M}(\mathrm{n}), \mathrm{M}(1))$ to be $\phi_{\mathrm{n}}$.

Each operad gives rise to a monad. To see this, we identify each natural number $n \in \mathbb{N}$ with the set $\{0,1, \ldots, \mathrm{n}-1\}$ and so obtain the natural sequence nat $: \mathbb{N} \longrightarrow$ Set. Left Kan extension along the functor nat gives a functor
given by $\operatorname{Ser}(\mathrm{p})=\mathrm{P}$, where

$$
\mathrm{P}(\mathrm{X})=\sum_{\mathrm{n} \geq 0} \mathrm{p}_{\mathrm{n}} \times \mathrm{X}^{\mathrm{n}}
$$

is the power series with coefficient sets $\mathrm{p}_{\mathrm{n}}, \mathrm{n} \geq 0$. There is a monoidal structure on the category Set ${ }^{\text {Set }}$ of endofunctors of Set given by composition of functors. A standard
calculation with power series shows that Ser is a strong monoidal functor; that is, it coherently preserves the monoidal structures:
if $P=\operatorname{Ser}(p), Q=\operatorname{Ser}(q)$ then $P \circ Q \cong \operatorname{Ser}(p \circ q)$; also,
$\operatorname{Ser}(\mathrm{u})$ is isomorphic to the identity functor.
It follows that monoids $t$ in $\operatorname{Set}^{\mathbb{N}}$ are taken to monads $\mathrm{T}=\operatorname{Ser}(\mathrm{t})$ on the category Set. An algebra for the operad $t$ is defined to be an Eilenberg-Moore algebra for the monad $T=$ $\operatorname{Ser}(\mathrm{t})$.

Besides substitution product, there are of course other useful operations on sequences of sets. The sum $\mathrm{p}+\mathrm{q}$ of sequences $\mathrm{p}, \mathrm{q}$ is given pointwise by $(\mathrm{p}+\mathrm{q})_{\mathrm{n}}=\mathrm{p}_{\mathrm{n}}+\mathrm{q}_{\mathrm{n}}$; this is the coproduct of $p, q$ in the category Set ${ }^{\mathbb{N}}$ and, likewise, infinite sums can be considered. The convolution product $\mathrm{p} * \mathrm{q}$ of $\mathrm{p}, \mathrm{q}$ is given by $(\mathrm{p} * \mathrm{q})_{\mathrm{n}}=\sum_{\mathrm{i}+\mathrm{j}=\mathrm{n}} \mathrm{p}_{\mathrm{i}} \times \mathrm{q}_{\mathrm{j}}$. It is easy to see that the functor Ser : Set ${ }^{\mathbb{N}} \longrightarrow$ Set $^{\text {Set }}$ takes sum to coproduct and convolution product to product. We can identify each set $z$ with the sequence $z$ given by $z_{0}=z$ and $z_{n}=0$ for all $n>0$. Then each sequence $p$ of sets can be decomposed as a power series

$$
\mathrm{p} \cong \sum_{\mathrm{n} \geq 0} \mathrm{p}_{\mathrm{n}} * \mathrm{u}^{* \mathrm{n}}
$$

where $u^{* n}$ is the $n$-fold convolution power of the unit $u$ for substitution product.

Example 3 Let $u^{*}$ denote the terminal sequence of sets; that is, each set in the sequence is a singleton. This clearly has a unique operad structure. The monad $\operatorname{Ser}\left(u^{*}\right)$ on Set is given by the full geometric series

$$
X^{*}=\sum_{n \geq 0} X^{n}
$$

The elements of $X^{*}$ are written as words in the alphabet $X$. The algebras for the terminal operad are the Eilenberg-Moore algebras for the geometric series monad, and so are monoids (in Set with cartesian product).

Example 4 Let $z$ be any set. Consider the sequence $z+u$ of sets given by

$$
(z+u)_{n}= \begin{cases}z & \text { for } n=0 \\ 1 & \text { for } n=1 \\ 0 & \text { for } n>1\end{cases}
$$

There is a unique operad structure on $\mathbf{u}+\mathrm{z}$ for which the substitution $(\mathrm{z}+\mathrm{u})_{1} \times(\mathrm{z}+\mathbf{u})_{0}$ $\longrightarrow(\mathrm{z}+\mathrm{u})_{0}$ is the second projection. The monad $\operatorname{Ser}(\mathrm{z}+\mathrm{u})$ takes X to the monic polynomial $z+X$ of degree 1. The monad structure on $\operatorname{Ser}(z+u)$ is induced by the canonical monoid structure on the arbitrary set $z$ with respect to the coproduct as tensor product on Set. The algebras for the operad $z+u$ are sets $A$ together with a function
$\mathrm{z}+\mathrm{A} \longrightarrow \mathrm{A}$ whose restriction to A is the identity; that is, the algebras amount to functions $\mathrm{z} \longrightarrow \mathrm{A}$ out of z . The category of algebras is the category $\mathrm{z} /$ Set of sets under z .

Example 5 Any monad $T$ on Set admits a distributive law [Bk] with the monad $\operatorname{Ser}(\mathrm{z}+\mathrm{u})$ of Example 4; that is, there is a natural transformation $\lambda: \operatorname{Ser}(\mathrm{z}+\mathrm{u}) \circ \mathrm{T}$ $\longrightarrow T \circ \operatorname{Ser}(\mathrm{z}+\mathrm{u})$ satisfying axioms ensuring that T lifts to a monad on $\operatorname{Ser}(\mathrm{z}+\mathrm{u})$-algebras, and that $T \circ \operatorname{Ser}(\mathrm{z}+\mathrm{u})$ gains a monad structure whose algebras are the same as the algebras for the lifted monad; in this case, the category of these algebras is just the category $z /$ Set $^{T}$ of T-algebras under $z$. The component $\lambda_{X}: z+T(X) \longrightarrow T(z+X)$ of $\lambda$ at $X$ is constructed from the unit of $T$ at $z$ and $T$ of the inclusions of $z, X$ in $z+X$. Suppose now that $T=$ $\operatorname{Ser}(t)$ for some operad $t$. Then $T \circ \operatorname{Ser}(z+u)=\operatorname{Ser}(t \circ(z+u))$ for the operad $t \circ(z+u)$ calculated as follows:

$$
\begin{aligned}
(T \circ \operatorname{Ser}(u+z))(X) & =\sum_{n \geq 0} t_{n} \times(z+X)^{n} \\
& =\sum_{n \geq 0} t_{n} \times \sum_{m \leq n}\binom{n}{m} z^{n-m} \times X^{m} \\
& =\sum_{n \geq 0} t_{n} \times \sum_{m \leq n}\binom{n}{m} z^{n-m} \times X^{m} \\
& =\operatorname{Ser}(t \circ(z+u))(X)
\end{aligned}
$$

where $(t \circ(z+u))_{m}=\sum_{0 \leq n}\binom{n+m}{m} t_{n+m} \times z^{n}$. We shall not bother explicitly describing the substitution operation of $t \circ(z+u)$ except in the special case of the next example.

Example 6 As a particular case of Example 5, take $t=u^{*}$ to be the terminal sequence as discussed in Example 3. Then $T \circ \operatorname{Ser}(z+u)$ is the monad given by

$$
(T \circ \operatorname{Ser}(\mathrm{z}+\mathrm{u}))(\mathrm{X})=(\mathrm{z}+\mathrm{X})^{*}
$$

The operad $t \circ(z+u)=(z+u)^{*}$ is given by taking $(z+u)^{*}{ }_{m}$ to consist of those elements of the free monoid $(z+1)^{*}$ which are words in elements of $z$ and the symbol 0 with exactly m occurrences of 0 . For we have the natural bijection

$$
\begin{gathered}
(z+X)^{*} \cong \sum_{m \geq 0}(z+u)^{*} m \times X^{m} \\
\left.a_{0} x_{1} a_{1} x_{2} a_{2} \ldots a_{m-1} x_{m} a_{m} \stackrel{\mid}{\stackrel{\mid}{l}}\left(a_{0} 0 a_{1} 0 a_{2} \ldots a_{m-1} 0 a_{m}\right),\left(x_{1}, x_{2}, \ldots, x_{m}\right)\right)
\end{gathered}
$$

where the $a_{0}, a_{1}, \ldots, a_{m} \in z^{*}$ and $x_{1}, x_{2}, \ldots, x_{m} \in X$. We have the substitution functions

$$
\begin{gathered}
(\mathrm{z}+\mathrm{u})^{*} \times(\mathrm{z}+\mathrm{u})^{*} \mathrm{~m}_{1} \times(\mathrm{z}+\mathrm{u})^{*}{ }_{m_{2}} \times \ldots \times(\mathrm{z}+\mathrm{u})^{*}{ }_{m_{i}} \longrightarrow(\mathrm{z}+\mathrm{u})^{*} \mathrm{~m}_{1}+\mathrm{m}_{2}+\ldots+\mathrm{m}_{\mathrm{i}} \\
\left(\mathrm{a}, \mathrm{~b}_{1}, \ldots, \mathrm{~b}_{\mathrm{i}}\right) \longmapsto \mathrm{a}_{0} \mathrm{~b}_{1} \mathrm{a}_{1} b_{2} a_{2} \ldots a_{\mathrm{i}-1} b_{i} a_{i}
\end{gathered}
$$

where $a=a_{0} 0 a_{1} 0 a_{2} \ldots a_{i-1} 0 a_{i}$. The distinguished element of $(z+u)^{*}{ }_{1}$ is of course $0 \in 1$.

Proposition 1 Free monads on power series endofunctors of Set are all of the form $\operatorname{Ser}(\mathrm{t})$ for an operad t .

This will follow from Proposition 2 which we lead in to by recalling the result of Michael Barr (see [K3]) that the free monad on any endofunctor $P$ on Set is the monad generated by the underlying functor Set ${ }^{\mathrm{P}} \longrightarrow$ Set from the category of P-algebras and its left adjoint. Let P be a power series endofunctor of Set with coefficients given by the sequence $p$ of sets. We regard the elements of $p_{n}$ as $n$-ary operations. A $P$-algebra is a set A together with, for each $n \in \mathbb{N}$ and each $\omega \in p_{n}$ a function $A^{n} \longrightarrow A$ which is also denoted by $\omega$. The left adjoint of underlying functor Set $^{P} \longrightarrow$ Set can be described iteratively as we did earlier for the case $P=R$. Then the adjunction generates the free monad on P. We shall give another construction ${ }^{3}$ related to Example 6.

Consider the free monoid $(P(1)+X)^{*}$ on the set $P(1)+X$ and regard the set $\mathbb{Z}$ of integers as a monoid under addition. Let $\left(^{-}\right):(P(1)+X)^{*} \longrightarrow \mathbb{Z}$ be the monoid hor morphism given on generators by:

$$
\bar{x}=-1 \text { for all } x \in X \quad \text { and } \quad \bar{\omega}=n-1 \text { for all } \omega \in p_{n} .
$$

Call $\mathrm{a} \in(\mathrm{P}(1)+\mathrm{X})^{*}$ well formed when
(i) $\overline{\mathrm{a}}=-1$, and
(ii) $\mathrm{a}=\mathrm{bc}$ implies $\overline{\mathrm{c}}<0$.

Let $W_{p}(X)$ denote the subset of $(P(1)+X)^{*}$ consisting of the well-formed words. We can equip $W_{p}(X)$ with the structure of $P$-algebra by defining

$$
\omega\left(a_{1}, \ldots, a_{n}\right)=\omega a_{1} \ldots a_{n}
$$

for all $\omega \in p_{n}$ and $a_{1}, \ldots, a_{n} \in W_{p}(X)$. To see that $\omega a_{1} \ldots a_{n}$ is well formed notice that
(i) $\overline{\omega \mathrm{a}_{1} \ldots \mathrm{a}_{\mathrm{n}}}=\bar{\omega}+\overline{\mathrm{a}_{1}}+\ldots+\overline{\mathrm{a}_{\mathrm{n}}}=(\mathrm{n} \pm 1)+( \pm 1)+\ldots+( \pm 1)=-1$ and
(ii) if $\mathrm{a}_{\mathrm{i}}=\mathrm{b} \mathrm{c}$, then $\overline{\mathrm{ca}_{\mathrm{i}+1} \ldots \mathrm{a}_{\mathrm{n}}}=\overline{\mathrm{c}}+\overline{\mathrm{a}_{\mathrm{i}+1}}+\ldots+\overline{\mathrm{a}_{\mathrm{n}}}=\overline{\mathrm{c}}+(-1)+\ldots+(-1)=\overline{\mathrm{c}}+(\mathrm{i}-\mathrm{n})<0$.

Proposition $2 \mathrm{~W}_{\mathrm{p}}(\mathrm{X})$ is the free P -algebra on the set X .

Proof Given a function $f: X \longrightarrow A$ into a P-algebra $A$, we must show that there exists a unique extension of $f$ to a P-algebra homomorphism $g: W_{p}(X) \longrightarrow A$. That is, we must show that the equations

$$
\begin{aligned}
& g(x)=f(x) \text { for } x \in X, \\
& g\left(\omega a_{1} \ldots a_{n}\right)=\omega\left(g\left(a_{1}\right), \ldots g\left(a_{n}\right)\right) \text { for } \omega \in p_{n} \text { and } a_{1}, \ldots, a_{n} \in W_{p}(X),
\end{aligned}
$$

[^1]uniquely determine $g$ satisfying the equations. To define $g(a)$ for $a \in W_{p}(X)$, we use induction on the number $r$ of occurrences of elements of $P(1)$ in the word a. By well formedness, if $r=0$ then $a \in X$ and the definition $g(a)=f(a)$ is forced. Suppose $r>0$. By well formedness, a must have length $>1$; so put $a=t b$ where $t \in X+P(1)$. But $\bar{b}<0$ and $\bar{t}+\bar{b}=-1$; so $\bar{t}>-1$; so $t \in p_{n}$ for some $n=-\bar{b}$ and we can write $b=c_{1} \ldots c_{n}$ where $\overline{c_{1}}=\ldots=\overline{c_{n}}=-1$. Since $a$ is well formed, it follows that $c_{1}, \ldots, c_{n} \in W_{p}(X)$. Define
$$
g(a)=\omega\left(g\left(c_{1}\right), \ldots g\left(c_{n}\right)\right)
$$
as we are forced to, and can do since each $c_{i}$ has fewer than $r$ occurrences of elements of $\mathrm{P}(1)$. It remains to prove that g is a P -algebra homomorphism, but that is a direct inductive argument. Q.E.D.

To construct the operad from $W_{p}$, notice that $\mathbb{N}$ becomes a P-algebra by taking each n -ary operation to be n -fold addition. Then we obtain a P-algebra homomorphism

$$
\gamma: \mathrm{W}_{\mathrm{p}}(1) \longrightarrow \mathbb{N}
$$

which restricts to the function $1 \longrightarrow \mathbb{N}$ whose value at the one element 0 of 1 is $1 \in \mathbb{N}$. So $\gamma(\mathrm{a})$ is the number of occurrences of the element 0 of 1 in the word a. Let $t_{n}=\gamma^{-1}(n)$ be the fibre of $\gamma$ over $n$. If we put $z=P(1)=p_{0}+p_{1}+p_{2}+\ldots$ we see that $W_{p}$ is a submonad of the monad $\operatorname{Ser}(\mathrm{z}+\mathrm{u})^{*}$ described in Example 6. Furthermore, the gradings are respected so that $t$ is a suboperad of $(z+u)^{*}$.

Corollary 1 The operad t is free on the sequence p of sets. The monad $\mathrm{T}=\operatorname{Ser}(\mathrm{t})$ is free on the endofunctor P .

Proof Suppose $o$ is an operad and $\theta_{n}: p_{n} \longrightarrow o_{n}$ are functions for all $n \geq 0$. We can make $\sum_{m \geq 0} \mathrm{o}_{\mathrm{m}}$ into a P-algebra by defining, for each $\omega \in \mathrm{p}_{\mathrm{n}^{\prime}}$ a function

$$
\omega:\left(\sum_{\mathrm{m} \geq 0} \mathrm{o}_{\mathrm{m}}\right)^{\mathrm{n}}=\sum_{\mathrm{m}_{1}, \ldots, \mathrm{~m}_{\mathrm{n}}} \mathrm{o}_{\mathrm{m}_{1}} \times \ldots \times \mathrm{o}_{\mathrm{m}_{\mathrm{n}}} \longrightarrow \sum_{\mathrm{m} \geq 0} \mathrm{o}_{\mathrm{m}}
$$

by $\omega\left(v_{1}, \ldots, v_{n}\right)=\theta_{n}(\omega)\left[v_{1}, \ldots, v_{n}\right]$. By Proposition 2 , there is a unique P-algebra homomorphism $\phi: \mathrm{W}_{\mathrm{p}}(1) \longrightarrow \sum_{\mathrm{m} \geq 0} \mathrm{o}_{\mathrm{m}}$ determined by $\phi(0)=1 \in \mathrm{u}_{1}$. This clearly respects the gradings and so gives functions $\phi_{n}: t_{n} \longrightarrow o_{n}$. Since $\phi$ is a P-algebra homomorphism, the functions $\phi_{\mathrm{n}}, \mathrm{n} \in \mathbb{N}$, commute with the substitution operations and $\phi_{1}$ preserves the distinguished object. So $\left(\phi_{\mathrm{n}}\right)$ is the unique operad morphism extending ( $\theta_{\mathrm{n}}$ ).

The free monad on the endofunctor P on Set is the monad generated by the underlying functor Set $^{\mathrm{P}} \longrightarrow$ Set and its left adjoint. By Proposition 2, this left adjoint is
provided by $W_{p}$. It is easily seen that the monad structure transports across our isomorphism $W_{p} \cong \operatorname{Ser}(\mathrm{t})$ to the monad structure induced by the operad t . Q.E.D.

In particular, taking the sequence $r$ of sets given by $r_{n}=0$ for $n=0,1$ and $r_{n}=1$ for $\mathrm{n} \geq 2$, so that the power series endofunctor $\operatorname{Ser}(\mathrm{r})$ is $R$, we obtain a parengebra isomorphism

$$
W_{\mathrm{r}}(\mathrm{X}) \cong \mathrm{F}(\mathrm{X}),
$$

an operad structure on $k$ producing the monad structure on $K=\operatorname{Ser}(k)$. (A topological version of $k$ is the Stasheff $A_{\infty}$-operad.)

We shall make a connection with free monoidal categories on certain ${ }^{4}$ tensor schemes [JS]. Take $\mathrm{p} \in \operatorname{Set}^{\mathbb{N}}$. Consider the tensor scheme $\mathcal{D}_{\mathrm{p}}$ with one object D and one arrow

$$
\omega: \mathrm{D}^{\otimes \mathrm{n}} \longrightarrow \mathrm{D}
$$

for each natural number $n$ and each $\omega \in \mathrm{p}_{\mathrm{n}}$. We represent the arrow $\omega$ by a planar string diagram where there are $n$ input strings above the node $\omega$ and 1 output string below ${ }^{5}$.

Let $\mathcal{D}_{\mathrm{p}}{ }^{*}$ denote the free strict monoidal category on the tensor scheme $\mathcal{D}_{\mathrm{p}}$ : the objects are of the form $\mathrm{D}^{\otimes \mathrm{n}}$ for $\mathrm{n} \in \mathbb{N}$ and the arrows can be identified with the deformation classes of planar string diagrams generated by those representing arrows of $\mathcal{D}$. Write $\operatorname{Mon}\left(\mathcal{D}_{\mathrm{p}}{ }^{*}\right.$, Set) for the category of (strong) monoidal functors from the monoidal category $\mathcal{D}_{\mathrm{p}}^{*}$ to Set with its cartesian monoidal structure. Clearly there is an equivalence of categories

$$
\operatorname{Set}^{\mathrm{P}} \longrightarrow \operatorname{Mon}\left(\mathcal{D}_{\mathrm{p}}{ }^{*}, \operatorname{Set}\right)
$$

Corollary 2 If t is the free operad on the sequence p of sets then there is a monoidal isomorphism

$$
\mathcal{D}_{\mathrm{p}}^{*} \simeq \mathcal{V}_{\mathrm{t}}
$$

taking D to 1 and $\omega: \mathrm{D}^{\otimes \mathrm{n}} \longrightarrow \mathrm{D}$ to $\omega 0 \ldots 0 \in \mathrm{t}_{\mathrm{n}}=\mathcal{V}_{\mathrm{t}}(\mathrm{n}, 1)$ for $\omega \in \mathrm{p}_{\mathrm{n}}$.

Proof We must prove that, given a strict monoidal category $\mathcal{A}$, an object A of $\mathcal{A}$, and

[^2]an arrow $f_{\omega}: A^{\otimes n} \longrightarrow A$ for each $\omega \in p_{n^{\prime}}$ there exists a unique strict monoidal functor $M$ : $\mathcal{V}_{\mathrm{t}} \longrightarrow \mathcal{A}$ with $\mathrm{M}(1)=\mathrm{A}$ and $\mathrm{M}(\omega 0 \ldots 0)=\mathrm{f}_{\omega}$. Since t is the free operad on p , there is a unique operad morphism $\phi: \mathrm{t} \longrightarrow \mathcal{A}(\mathrm{A})$ (see Example 1) whose restriction to p is given by $\omega \longmapsto \mathrm{f}_{\omega}$. By Example 2, this operad morphism determines a strict monoidal functor M as required. Q.E.D.

The arrows of $\mathcal{D}_{\mathrm{p}}{ }^{*}$ can be identified with p-labelled (planar) forests. To see this, recall from [JS] how the general string diagrams are built from the generators in $\mathcal{D}_{\mathrm{p}}$. We take some arrows from $\mathcal{D}_{\mathrm{p}}$ and some identity strings and tensor them; this amounts to placing the representing string diagrams next to each other. Here are two examples.

Next we stack such diagrams vertically splicing each lower loose string of one diagram with precisely one upper loose string of the diagram below. The two example diagrams are composable and the composite is represented as follows.

But such a planar diagram can be replaced by a more combinatorial structure. We can
represent this last composite by a diagram

where we have removed the bottom loose strings, put square nodes on the top loose strings, and shortened the strings so that they connect nodes of consecutive height. We must remember that, although we have omitted it from the diagram, each round node with $n$ strings attached at top is labelled by an element of $p_{n}$. The structure that arises in this way is precisely a planar forest; that is, a functor $\mathrm{f}:[\mathrm{k}]^{\mathrm{op}} \longrightarrow \Delta$ where $\Delta$ is the category whose objects are the linearly ordered sets $[k]=\{0,1, \ldots, k\}^{6}$ and whose arrows are order-preserving functions. Such a functor gives linearly ordered sets $f(i)$ for $0 \leq i \leq k$ (whose elements are called vertices of $f$ of height i) and order-preserving functions $f_{i}$ : $f(i+1) \longrightarrow f(i)$ for $0 \leq i<k$. In our example, $f(0)=[5], f(1)=[6], f(2)=[7], f_{0}(0)=f_{0}(1)=1$, $\mathrm{f}_{0}(2)=\mathrm{f}_{0}(3)=\mathrm{f}_{0}(4)=3, \mathrm{f}_{0}(5)=\mathrm{f}_{0}(6)=5, \mathrm{f}_{1}(0)=\mathrm{f}_{1}(1)=\mathrm{f}_{1}(2)=0, \mathrm{f}_{1}(3)=\mathrm{f}_{1}(4)=3, \mathrm{f}_{1}(5)=\mathrm{f}_{1}(6)$ $=f_{1}(7)=6$. A forest $f:[k]^{\text {op }} \longrightarrow \triangle$ is called a tree when $f(0)=[0]$. Each forest can be identified with a linearly ordered set of component trees: the number of component trees is n where $\mathrm{f}(0)=[\mathrm{n}-1]$.

For a forest $\mathrm{f}:[\mathrm{k}]^{\mathrm{op}} \longrightarrow \Delta$ of height k , a vertex $\mathrm{v} \in \mathrm{f}(\mathrm{i})$ is called a leaf when the fibre of $f_{i}$ over $v$ is empty. Notice in our example that the square nodes are all leaves; but there are also two round nodes that are leaves. Let p be a sequence of sets. A labelling of a forest $f$ in $p$ assigns to each vertex $v \in f(i)$, which is not a leaf, an element $\omega(v) \in p_{n}$ where $n>0$ is the cardinality of the fibre of $f_{i}$ over $v$, and assigns to some leaves $v \in f(i)$, which are not of height $k$, an element $\omega(v) \in p_{0}$. A leaf which is not labelled will be called fallen; so all leaves of height $k$ are fallen. A forest together with a labelling in $p$ will be called a p-forest.

This leads to our new view of the strict monoidal category ${ }^{7} \mathcal{D}_{\mathrm{p}}{ }^{*}$. We see that the arrows $D^{\otimes m} \longrightarrow D^{\otimes n}$ can be identified with p-forests having $m$ fallen leaves and $n$ vertices of height 0 . The tensor product of two p-forests is given by placing them next to each other in the plane; we shall not describe it combinatorially. Composition is given by grafting: we shall just give an example. Let us take the following example of two

[^3]composable p-forests.

( $\mu$

Their composite is the following p-forest in which the component trees of the top forest are grafted on at the fallen leaves of the bottom forest.

(1)

From this, we deduce another view of the free operas $t$ on $p$ in which elements of $t_{n}$ are identified with p-trees with n fallen leaves.

A view of $\mathcal{D}_{\mathrm{p}}{ }^{*}$ that even a computer can understand can be obtained using rewrite systems [S]. The basic p-forest

can be identified with triplets $(1, \omega, r)$ where $1, m, r$ are natural numbers and $\omega \in p_{m}$. Consider the directed graph $\mathcal{G}_{\mathrm{p}}$ whose vertices are natural numbers and whose edges are the expressions

$$
(\omega, r): a \longrightarrow b
$$

where $a, b, r$ are natural numbers such that $r<b \leq a+1$ and $\omega \in p_{m}$ where $m=a-b+1$. The idea is that each $\omega \in \mathrm{p}_{\mathrm{m}}$ is regarded as the name of a (first-order) rewrite rule and ( $\omega, \mathrm{r}$ ) $: a \longrightarrow b$ represents an allowable application of the rule; $l=b-1-r$ and $r$ are the left and right "whiskers", respectively. We introduce some (second-order) rewrite rules on directed paths in the graph $\mathcal{G}_{\mathrm{p}}$.

$$
\xrightarrow[{a \xrightarrow{(\omega @ \mathrm{r} @ \mathrm{a}-\mathrm{b})} \mathrm{b} \xrightarrow{(\omega, \mathrm{r})} \mathrm{a}-\mathrm{b}+\mathrm{c} \xrightarrow{(\omega, \mathrm{r})} \mathrm{c}}]{\mathrm{a}} \mathrm{c} \text { for } \mathrm{r}<\mathrm{r} \text { C }
$$

It is easy to see that the p-forests corresponding to the top and bottom of this rewrite rule are equal. Two directed paths in $\mathcal{G}_{p}$ with same source and target are said to be equivalent when there is a sequence of applications of the (second-order) rewrite rules which takes one path to the other. A directed path

$$
a_{0} \xrightarrow{\left(\omega_{1}, r_{1}\right)} a_{1} \xrightarrow{\left(\omega_{2^{\prime}} r_{2}\right)} \ldots \xrightarrow{\left(\omega_{n^{\prime}} r_{n}\right)} a_{n}
$$

is said to be in normal form when $r_{i} \geq r_{i+1}$ for $1 \leq i<n$. Each directed path is equivalent to a unique path in normal form; indeed, the normal form can be achieved by directed applications of the (second-order) rewrite rules (the proof of confluence and termination is similar to the case considered in [S]).

In this way, we obtain a strict monoidal category isomorphic to $\mathcal{D}_{\mathrm{p}}{ }^{*}$. The objects are natural numbers and the arrows are equivalence classes of directed paths in $\mathcal{G}_{p}$. The composition is induced on equivalence classes by concatenation of paths. The tensor product $\mathrm{a} \otimes \mathrm{b}$ is given on objects $\mathrm{a}, \mathrm{b}$ byaddition $\mathrm{a}+\mathrm{b}$ of natural numbers. The functor $c \otimes-$ is given on arrows by

$$
\mathrm{c} \otimes\left[\left(\omega_{n^{\prime}} \mathrm{r}_{\mathrm{n}}\right) \circ \ldots \circ\left(\omega_{1}, \mathrm{r}_{1}\right)\right]=\left[\left(\omega_{\mathrm{n}^{\prime}} \mathrm{r}_{\mathrm{n}}\right) \circ \ldots \circ\left(\omega_{1}, \mathrm{r}_{1}\right)\right]
$$

and the functor $-\otimes d$ is given on arrows by

$$
\left[\left(\omega_{n^{\prime}} r_{n}\right) \circ \ldots \circ\left(\omega_{1}, r_{1}\right)\right] \otimes d=\left[\left(\omega_{n^{\prime}} r_{n}+d\right) \circ \ldots \circ\left(\omega_{1}, r_{1}+d\right)\right]
$$

the tensor product $\pi \otimes \rho: a \otimes c \longrightarrow b \otimes d$ of two arrows $\pi: a \longrightarrow b, \rho: c \longrightarrow d$ is then given by either route around the following square, the commutativity of which is precisely what we have achieved by our equivalence relation on paths.

We now want to define an order inspired by the order on $F(X)$ coming from the Stasheff polytopes. Suppose the sequence p of sets is equipped with a "substitution into the i-th position" operation

$$
\operatorname{sub}_{\mathrm{i}}: \mathrm{p}_{\mathrm{m}} \times \mathrm{p}_{\mathrm{n}} \longrightarrow \mathrm{p}_{\mathrm{m}+\mathrm{n}-1}
$$

for $1 \leq \mathrm{i} \leq m$, written $\operatorname{sub}_{\mathrm{i}}(\omega, \tau)=\omega \wedge_{\mathrm{i}} \tau$. This allows us to define an order on the sets $W_{p}(X)$. Let $\leq$ be the smallest reflexive transitive relation such that $a \omega b \tau c \leq a\left(\omega \wedge_{i} \tau\right) b c$ whenever $\omega, \tau \in \mathrm{P}(1)$ and b is a product of $\mathrm{i}-1$ well-formed elements of the monoid $(P(1)+X)^{*}$. Notice that, under these conditions, $a \omega b \tau c$ is well formed iff $a\left(\omega \wedge_{i} \tau\right) b c$ is well formed. Also, the order is antisymmetric and satisfies the ascending chain condition (since the length of the word $a\left(\omega \wedge_{i} \tau\right) b c$ is one less than the length of $\left.a \omega b \tau c\right)$. The number of elements of $X$ occurring in the word $a \omega b \tau c$ is the same as in $a\left(\omega \wedge_{i} \tau\right) b c$; so the order respects the grading $\gamma: W_{p}(1) \longrightarrow \mathbb{N}$, yielding a sequence $t$ of partially ordered sets $t_{n}$, $\mathrm{n} \geq 0$.
